Abstract

Our study based on determining factors that affect the function of demand for money in the Malaysian economy over 1970-2018 based on time-series data collected from WDI (World Bank). We tacitly include real CPI, real interest rate, financial innovation, real GDP, and implied the ARDL Bound tests. Derived from empirical evidence, we revealed that financial innovation has quite a significant and positive impact on the short-term. In contrast, real GDP has a negative and meaningful relationship with real money demand function in Malaysia. The official real exchange rate has a positive and significant relationship with real-money demand, with an increase in the real exchange rate of one unit, boosting the long-term function with money demand by 0.97. Negative and significant relationships revealed that by raising 1% real GDP dissecting to decrease real money demand by 0.6395 in the Malaysian economy. Eventually, real money demand anticipated 13.0796 once all independent variable in the Malaysian economy is zero.

Keywords: Real Money Demand, Financial Innovation, RGDP.

Introduction

During the contemporary eras, through intention to establishing and analysis to the accomplishment of money demand function (Md) steadiness, the number of studies steered which intended research scholars and academics from developed and developing

¹ Corresponding author’s email: muhammad.mazher@s.unikl.edu.my
states for exploration and policy establishment concerned with money demand function. Exclusively, the consequence and importance in regards to inference particularly apprehensive through policy formation with assuring that monetary policies directed expertly argued by (Arango and Nadiri, 1981), (Bahmani-Oskooee and Tanku, 2006), (Hoffman et al., 1995). The importance of money demand functions explicitly for the federal bank because it examines the money supply (Ms) growth rate objectives during the medium-term and also observes total liquidity through interest rate and manipulation in the money reserve described by (Treichel, 1997). According to the researcher, to attain a stable money demand function, there is a need for sound monetary policy. Conversely, the unstable money demand function concludes significance for financial reforms and a rise in new financial assets appearance that direct to incompatibility among targets of monetary growth, real economic growth, growth of money supply, and wrongly besets monetary aggregates to imitate an economy's total liquidity. The money held by the private sector is called "monetary demand." The two main functions of money which may create the source of detention include tasks such as "means of exchange" and "store value." (Bitrus, 2011) described the demand for money as a means of exchange.

It shows that while trade facilitated, money produces prosperity as a function of accumulated value. Therefore, the concept of money demand function plays a dynamic and essential role in monetary economics. (Sichei and Kamau, 2012) conferred the significance of demand for money variables for academic scholars. They referred to the cause of importance that is very much concerned with the monetary policy framework compiling variable. The great attention is given by monetary policy towards the demand for money concepts because of its virtuous controlling with led to sufficient monetary policy implications and ultimately revealed a positive and significant impact on the economy by this process. Mainly M_d function is essential to the realization process of physical money market awareness while executing real monetary policy by any country. A reliable, optimal monetary policy never described by economists while the remarkable money demand function absence in their estimates. Capable money unified contextual plays a robust role in any economy's long-run economic potentials, and projections undertake parts comprise, delivers information regarding investment, and allows mobilization and merging savings and capital provision. It confirms monitoring about investment and corporate governance proceeding to debt capital, ease trading, broadening and management hazard, and lastly, but not least comfort exchange of goods & services.

(Friedman, 1956) described that money demand work confirms a static a long-time ago balance interaction between money adjusts, excellent pay, and open door cost of keeping genuine adjusts, which considered work demand for money. Since the presentation of the cointegration investigation through (Engle and Granger, 1987), this relationship has acquired a boosting consideration, especially the solidness problem of financial experts. They have warred about changes in the demand for money, on account that demand stuns can impact yield changeability and have recommendations for fiscal approach. For instance, (Kontolemis, 2002) communicates, soundness of considering the long term in the past run money demand for paintings is a massive factor for the intention that a long time ago run development paces of fiscal factors.

Real money demand can be divided theoretically into three types of transaction, precautionary, and speculative demands. In theory, the demand for transactions (purchases
operations) shows a positive association with income and a harmful linking with interest rates. The precautionary demand occasioned a definite (positive) proportion to income, and a negative ratio resulted in speculation and interest rates. Subsequently, real-world practices showed the value of credit does matter for developing economies, meanwhile in emerging economies, the transaction through M2 (broad money) impartially frequently takes place. For smooth and development related activities, government, business owner, and investor always used credit for lending facilities. Financial institutions, including banking sectors, create money through loaning or providing credit to individuals and organizations.

Nevertheless, during the boom and when returns on investments are high, this situation leads to enhancement in lending and borrowing activities comparative to lower cost of credit. Inversely, during the economic crises (inflations or deflation), the financial institutions demoralize the borrowing activities by charging a high rate of interest. Hence, (Yu and Gan, 2009) exposed that when the cost of borrowing rises, demand for money decreases in any economy. According to (Wihardja, 2013), as the national blueprint, the Malaysian economy has incorporated the ASEAN. Hence, the financial sector transformed into additionally de-regulated as well as market-oriented, which leads to international integration and more liberalization described by (Bank Negara Malaysia, 2011).

Moreover, (Noman et al., 2017) explained that comparative to four ASEAN economies, the cost-to-income formation of banking operations in Malaysia by various financial institutions and banks led to more efficiency. Thus, financial reforms make the cause of the effect of monetary targeting performance. Numerous influential studies comprise (Ghaffar et al., 1987); (Rahim, 1986); (Semudram, 1981) discussed on demand for money related topics in the Malaysian economy. These researches implied partial adjustment description commonly rather than analyzing the series properties and cointegration methods. (Tseng and Corker, 1991) analyzed on various problems that comprise financial liberalization impact through concentrating on instability causes over the 1980s era. More, the researchers studied whether exchange rate factors could be utilized being a determinant of demand for money function to measure stability motive in the long-run.

Finally, based on several searches of empirical and theoretical literature, we have proposed broad money (M2) as a proxy for money called M\textsubscript{d}, CPI, real interest rate and financial innovation as a proxy of domestic credit to the private sector by banks as % of GDP and real GDP.

**Literature Review**

**Theoretical Review**

An item, element, or thing having worth and legal tender to payback domestic and international debt obligations, utilized for investment purposes, means in exchange in finance, using for financial records, etc. is considered as money. It always induced by the government of the country under the legal tender. Bank money and legal tender are two basics sources of money creation in any economy. The value or worth in the form of money of goods is called its nominal value. Money values in several years of somewhat are called nominal values in economic theory. More specifically, the effect of the nominal
value of the time series is recognized as the real value to obtain a critical image of economic trends, eliminating changes in price levels.

Although real values can define as the value or worth in the form of some other goods, services, and the basket of goods, etc. Real values regulate for transformation or differences in the price level in those years or more simply the values adjusted for inflation are known as real values. For the real price of goods and services, there is another term known as 'real price.' When an individual talk about the 'relative price' of laptop has dropped during recent years, it direct to the price of laptop relative to or restrained in term of other goods & services like LCD, Motorbike or car, etc. has deteriorated. During inflation, if nominal prices increase, relative prices of individual products & services can desire. The purchasing power of money is called real money. Due to inflation, there are frequent variations in the value of real money. Various companies can make the right decision if they estimate their performance in real money terms, meanwhile considered capital opportunity cost and inflation. State of the economy showed by money supply expected in terms of nominal in any country. The financial innovation, real GDP, interest rate and price level may be the cause of money quantity hold by individuals. (Bara and Mudzingiri, 2016) identified two indicators of financial innovation, which include a broader monetary relationship, narrow money (M2 / M1), and a banking sector with a private sector (interest rate) to GDP. As a percentage of GDP

**Real Money Demand (M/P)**

The relationship between money quantity and the price level is the concept of real demand for money. The amount may include a nominal amount (M1) or a narrow amount (M2). In a monetary economy, the own desire for financial assets in the form of money is called real demand for money. It may comprise cash and bank deposits (excluding investment). Narrowly it is a notion as M1 (Directly spendable assets – Checkable deposits and money in circulation includes in M1 category) and in the broad sense as M2 (It comprise M1 + Saving Deposits (< $100K) + Money market mutual funds) and M3 (It comprise M2 + Large bank deposits).

**The Price Level (Consumer Price Index - CPI)**

Monetary Set (M1) or nominal money is measure in dollars, and the CPI and the amount of money also called money demand, are proportional. For instance, in the case of 10% in prices, individuals will hold more than 10% of the money for purchasing the same goods bundle. i.e., if an individual purchases the cup of coffee with some sacks at $10 earlier, now he will need more $1 to hold within for purchasing the same. "Real money" measured in dollars. What it will buy, does it estimate? The quantity of real Md remnants self-determining of the price level.

**The Interest Rate**

The rate of interest which a private may be earned on assets holds as an alternate of cash/money referred to as opportunity cost of keeping money. It has an inverse relationship between opportunity cost and Md, or in other words, when the interest rate, which is the cost of opportunity, is high, it will lead to less demand for money (Md).
**Real GDP**

Planned spending directly to money holding. In any economy, the quantity of $M_d$ is contingent toward real GDP generally. Hence, a high level of expenditure because of high income, individuals hold an abundant amount of money with them for higher-spending volume.

**Financial Innovation**

Quantity of money seized gets affected by the transformation in technologies. It involves a day-to-day interest in checking deposits, automatic transfers between checking and saving deposits, ATM, credit cards. Generally, the demand for money ($M_d$) being compact in the above innovations.

**Money Demand Curve**

The relationship between the interest rate and real money demand can be illustrated through the money demand curve. It can be studied through the diagram – A.

(Diagram – A)

(Diagram – B)

According to diagram – B, due to variations in real GDP and financial innovations, fluctuations occurrence in $M_d$ and resultantly moves occurred in the real $M_d$ curve. Three crucial motives comprise transactional, precautionary, and asset demands to keep money
by individuals with them. Term ‘transaction demand’ recognized and familiarized by classical economists and Keynes (1936) trailed by the ‘theory of liquidity preference’ presented by classical school of thought. It may be clarified as the money held for the exchange to make payment. It contains money stock. The individual keeps with them for anticipated day-to-day expenditures. The negative relationship exposed between transactional demand and interest rate by (Baumol, 1952) and (Tobin, 1956). Individuals minimize their money holding for transaction motives once the rate of interest deteriorates because of the opportunity of money holding intensify. Precautionary demands may explain as the money holding for impulsive or emergency expenses, and these transactions are proportional to income. If incomes increase, these balances also rise to attain the same protection level of safety. Therefore, the negative relationship between the precautionary demand and the interest rate is confirmed.

(Keynes, 1936) described that an individual always having faith in normal interest rate value. If the interest rate remains at a low level, it led to prediction to increase in the interest rate and bond price by the peoples. Individuals suffer a capital loss if and only if, there is a decrease in bond price compensate the interest gain. Zero return of money outstrips bonds negative returns as of demand for money by an individual's. In the case of the high current rate of interest, individuals forecast price rises for relationships and interest rate reduction. If a fall in interest rate compensates by an increase in bond price, individuals gain capital. Resultantly, people's demand for money minimum because of return on money surpasses to zero, and finally, the negative relationship exposed between speculative or asset demand and interest rate. The amount of money demanded transaction motives remains constant at a given level of income. The holding money opportunity cost makes the reason for the determination of the precautionary or asset demand. The following diagram - C is showing the demand for money curve.

(Diagram – C)

**Determination of Interest Rate in Money Market**

The rate of interest may conclude through the contact between money demands (M₃) and money supply (Mₛ) – see diagram D. The point of interaction confirms the rate of interest. Keynes, in his ‘theory of liquidity preference’ described that modifications in
interest rate led to \( M_d \) and \( M_s \) in steadiness situation. Finally, the point of interaction between \( M_d \) and \( M_s \) also confirms the money market equilibrium. At any specific time, the Fed can affect the money supply (\( M_s \)); meanwhile, the quantity of real money supply is a constant (considered constant because it cannot increase or decrease immediately) or a fixed amount.

![Diagram D](image)

There are maybe various reasons for changing the interest rate comprise, Fed initiates to anxiety inflation, discouraging borrowing through increase interest rate, selling securities in the open market by Fed, through dropping bank's reserves, by issuing fewer new loans, and decreasing the money supply. See diagram-E.

![Diagram E](image)

**Quantity Theory of Money**

During the long-run, prices increased by increases in monetary growth; nonetheless might be little or no effect on productivity explained by Milton Friedman (1956). He argued that under the short-run, production and employment level increased due to the
rise in growth of Ms, through a decrease in money supply growth, employment and production dropped. According to Milton Friedman, it is always and even everywhere monetary miracles. Hence, the price level (P) determined by the available quantity of money (Qm), and likewise, the inflation rate firm through the Qm available.

Formation of surplus supply of money (Ms) is the upshot of an immediate consequence of a rise in Ms. It must be remembered that increase in money held by the individuals does not mean that it is the result of an increase in Ms. It works in a process as, by lessening interest rate, money demand (Md) increases. Individuals attempt to release this excess Ms in various customs comprise purchasing goods and services with surplus funds and to make loans to others. More, assume that credits amounts may be exploit for buying products and services since the supply of goods had not changed. Finally, prices move upwards because the demand for goods & services increases in the economy. How many times a distinctive dollar bill employed for compensation of newly-produced products and services in a year, is another interpretation of quantity theory of money.

Formation of surplus supply of money (Ms) is the upshot of an immediate consequence of a rise in Ms. It must be remembered that increase in money held by the individuals does not mean that it is the result of an increase in Ms. It works in a process as, by lessening interest rate, money demand (Md) increases. Individuals attempt to release this excess Ms in various customs comprise purchasing goods and services with surplus funds and to make loans to others. More, assume that credits amounts may be exploited for buying products and services since the supply of goods had not changed. Finally, prices move upwards because the demand for goods & services increases in the economy. How many times a distinctive dollar bill employed for compensation of newly-produced products and services in a year, is another interpretation of quantity theory of money.

**Empirical Literature Review**

According to (Kombo and Nyangoro, 2019), his research analysis founds the real money-demand function for Kenya and examine its steadiness in the attention of quick development of financial innovations and efficiency of monetary policy. Based on quarterly data empirical analysis, through implying Engle-Granger, VECM researchers establish cointegration and revealed structural breaks in Kenya's real money demand function. The outcomes show that the interest rate does not distress the demand for real money balances. In contrast, local domestic asset holders encourage to hold interest in earning financial assets as a substitute for cash balance during the short-run period. Researchers suggest the usage of substitute monetary policy context, which is not based on money supply aggregates, like nominal GDP targeting alone or in grouping with others to attain goals of monetary policy. (Narayan et al., 2009) Estimate the money demand function of the SAC group (South Asian countries), including Bangladesh, India, Pakistan, Sri Lanka, and Nepal from 1974 to 2002. Researchers exposed factors that influence real income, real exchange rates, and domestic and short-term foreign currency interest rates. Taken together, these signs give a clear indication of the long-term elasticity of a statistically significant relationship between money demand and its drivers. (Ahmad and Munirs, 2000), studied the phenomena regarding money-demand in Pakistan from 1972 to
1996. The outcome leads to the inflation rate instead of interest rate that might be contacted in regards to steady money-demand. More, a lot of adjustments in money-demand are implanting by monetary establishments to track money market steadiness.

According to (Anwar and Asghar, 2012), defeating the financial and economic variation is the strategic and fundamental task for monetary policy competency, and whatever variables stimulus the demand for money is the sound for effervescent information. Through involving real income, inflation, exchange rate, and real demand for money, an analysis conducted by applying the ARDL technique. The researcher revealed that M2 monetary aggregates co-integrated with their influential factors in terms of the long-run association seems by all accounts look like steady. The investigation recommends that monetary establishments and policymakers must concentrate just on long-run adjustment policy in Pakistan. (Darrat, 1985) discussed a central role of demand for money function is various economic theories regarding aggregate economic activity, particularly for establishing and implementation of any monetary policy. The researcher examines the developing economy of Kenya and evident the empirical outcome that conventional money definition, which based on narrow and broad, and theoretical model, fit on Kenya's economy very well. More, consequences direct that some of the measures concerning foreign interest rates play a significant key role in Kenya's money demand function. (Achsani, 2010) described that monetary policy always admitted the most critical element predicted steady money demand function while monetary aggregates are ever having significant intervention on output, interest rate, and level of prices. The researcher implied VECM and ARDL econometric techniques and estimation outcomes signpost that demand for real M2 money amassed was co-integrated with interest rate and real income in Indonesia for the period of 1990Q1 to 2008Q3. Real money demand revealed a positive relationship with real income for short and long-run period and interest rate exposed negative impression on M2 for long-run period.

(Skrabic and Tomic-Plazibat, 2009) studied the demand for real money in Croatia, time series analysis. Using Johansen’s cointegration test, VAR, and VECM techniques, the researchers established the uniqueness of the descriptive variable. The results show a slow rate of adjustment to eliminate inequality over the long term. Although interest rates have risen significantly in the short-term, industrial production and real exchange rates represent the demand for different types of money in the long run. (Chen, 1997) initiated a long-term money demand through M0 and M2, and the use of annual time series data from China from 1951 to 1991. Besides, it also responds to flexibility. Real money demand applies to M0 and M2 between 1.4 and 1.5 and 1.8 and 1.9, respectively. If Chinese inflation is less than 10%, the target M2 growth rate should not exceed 28% to 29%. (Choudhry, 1995) concluded that the three countries, including Argentina, Israel, and Mexico, support Johansen's steady cointegration long-term demand for finance function through joint integration. It happened only when the exchange rate (devaluation of the currency) assumed in the money demand function.

**Research Methodology**

An immediate concern comes across by policymakers in developed and developing economies predictable as stable money demand function. Several factors may include money demand function determination. It is very crucial to select the variable during the
construction of a model for money demand function. Proxies for financial innovation comprise M2/M1 (ratio between broad money to narrow money) and GBCP/GDP (credit growth in banking to private sectors as a proportion of GDP) assumed by (Bara and Mudzingiri, 2016). Hence, $M_d$ depends upon interest rate, real GDP, financial innovation, and price level. Likewise, considering currency alternative into account, numerous researchers analyzed demand for money ($M_d$) for developing economies and include variables most of the time named as 'exchange rate' when they defined their $M_d$ functions. Mundell (1963) insertion this variable s standard for money demand function initially.

$$\text{Real } M_d = \beta_0 + \beta_1 OEXR + \beta_2 RGDP + \beta_3 FI + \beta_4 RIR + \varepsilon$$

Here, Real $M_d$ referred as real money demand which is cliché over the ratio between broad money (M2) to real consumer price index (measured in P), OEXR as official exchange rate, RGDP as a real gross domestic product, FI as financial innovations (domestic credit to private sector by banks - % of GDP), and RIR as the real interest rate (lending interest rate adjusted for inflation as measured through GDP deflator). Our data set comprises yearly time series data from WDI (World Bank), over the period 1970-2018 for the Malaysian economy.

### Estimations and Results Discussions

**Unit-Root**

The motive to conduct the unit-root test was to confirm the integration-related properties of all variables. We involve the Phillip-Perron method to perform the unit-root analysis, which revealed the following stationary levels.

<table>
<thead>
<tr>
<th>Unit-root Results (Phillips-Perron Method)</th>
<th>Probability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable(s)</td>
<td>I(0)</td>

</tr>
</tbody>
</table>

The above unit-root table1 estimations revealed mixed behaviour of stationary comprise level and 1-st difference. Based on the above outcomes, it led to the application of ARDL Bounds testing techniques. Pesaran et al. (2001) initiated a new procedure named ARDL Bound Testing method. This relatively new and modern technique is cointegration techniques to form or study the long-run relationship between variables.

**Lag-Length Criteria**

Through implying VAR lag order selection criteria, we revealed table-2, which indicates lag-length 1 through various techniques comprise of AIC and SC.

**ARDL Bound Test**

The ARDL bounds test stated that the variables involved in our model are bound together in the long-run period. The following table-3 outcomes are revealing robust, strong long-run bonding among our model variables when the F-statistics value (11.43208) exposed more than the lower and upper limit of critical values bounds at a 5% level of significance.

</tbody>
</table>

The CointEq may write as:

\[
\text{Real Money Demand} = \frac{\text{LM2}}{\text{LRCPI}} = 13.074 - 0.342(LFI) + 0.975(\text{LOEXR}) - 0.629(\text{LRGDP}) + 0.276(\text{LRIR})
\]

Under the long-run period, a positive and significant relationship revealed between the official exchange rate and real money demand. It directs that, by increasing a 1% change in the official exchange rate, the real money demand predicted to increase by 0.9754 units. In contrast, there is a negative and significant relationship between real gross domestic product and real money demand. It leads that by an increase in 1% in real GDP, it predicted that real money demand decrease by 0.6395 units, and lastly real money demand predicted 13.0796 when all independent variable is zero in the Malaysian economy. See table – 5.

**Diagnostic Tests**

*Normality Test - Histogram*

Normality test conduct through a histogram (see diagram-F). It revealed that the probability value (0.0512) is more than 5% that confirms the normality condition satisfaction.
Serial Correlation Analysis

To check the problem of serial correlations existence, first, we undertake the null-hypothesis as there is no serial correlation. We implied Breusch-Godfrey serial correlation LM test. The following table-6 is revealing the results in which our null-hypothesis accepted because of Prob. The Chi-square value is more than 5%.

Table 6. LM Outcomes

<table>
<thead>
<tr>
<th>Breusch-Godfrey Serial Correlation – LM Test</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Observed $R^2$ = 1.3312</td>
<td>Probability Chi-square (2) = 0.5140</td>
</tr>
</tbody>
</table>

Heteroscedasticity Test

To check the presence of 'Heteroscedasticity' problems in our model (see table – 7), we implied the test named 'Breusch-Pagan-Godfrey heteroscedasticity test.' The estimation led to non-presence or absence of Heteroscedasticity problem.

Table-7 (Heteroscedasticity Outcomes)

<table>
<thead>
<tr>
<th>Breusch-Pagan-Godfrey Heteroscedasticity Test</th>

</tr>
</tbody>
</table>

CUSUM Tests – Model Fitness

CUSUM tests exposed the fitness of the estimated model. If the estimated line (blue line) remained inside the upper and lower limit (both red lines), we could say that our model is robust and fit. See diagram – G.
Conclusion

Our research study intended to distinguish the fundamental determinants dynamics for Malaysian money demand function. Through empirical analysis on various economic factors comprise, price level, interest rate, real GDP, and financial innovation as independent variables, we imply different econometric techniques including unit-root, ARDL bound test. We confirm the long-run bounding of all assumed variables through the ARDL bound test. Based on estimations consequences, we accomplish a positive and significant relationship for financial innovation. However, substantial and adverse contacts found for real GDP in regards to real money demand function for the Malaysian economy over 1970-2018. It directed to conclusions that financial innovation moves in the same direction with real money demand and its decisive factors while considering real money demand function in Malaysia for a short period.

On the other hand, real GDP is also a very imperative factor, but its movement with real money demand function in the opposite direction or both having an inverse relationship in the short-run phase in Malaysia. It concluded that a significant positive relationship exposed to the official real exchange rate and negative but significant for real GDP with real money demand for the Malaysian economy over the long-run phase. It means for an active real money demand function over the long-run period, Malaysian authorities need to engage an official real exchange rate as the determinant. Since, when the real exchange rate increases, and it may cause to increase in real Md. But, the real GDP showing an inverse relationship specifies, if Malaysian authorities decrease real GDP. It will make the cause of an increase in real money demand, and when real GDP of Malaysia increases, make the cause of diminishing real money demand function.
